

# Intro to Dynamic Programming (DP)

Presented by Alex Li

# What is DP?

Solving a problem by first making it harder.

# A classical conundrum

You can only go RIGHT or UP. How many ways are there to get from START to ~~END~~ EVERY OTHER SQUARE?

					END
START					

# A classical conundrum

You can only go RIGHT or UP. How many ways are there to get from START to EVERY OTHER SQUARE?

1	5	15			
1	4	10			
1	3	6	10	15	21
1	2	3	4	5	6
START	1	1	1	1	1

# The antihero - STATIC PROGRAMMING!

- I see Pascal's triangle...
- Answer is just  $\binom{9}{5}$
- Equal to number of ways to rearrange the sequence  
RRRRRUUUU

# The Generalizable approach - Blockades

You can only go RIGHT or UP, but not through black squares. How many ways are there to get from START to END?

					END
START					

# The Generalizable approach - Blockades

You can only go RIGHT or UP, but not through black squares. How many ways are there to get from START to END?

	3	6		11	27
	3	3	7	11	16
1	3		4	4	5
1	2	3	4		1
START	1	1	1	1	1

# The Generalizable approach - Blockades 2.0

How many ways are there to get from START to END?

# The Generalizable approach - Blockades 2.0

How many ways are there to get from START to END?

# The Generalizable approach - Optimizing

You can only go RIGHT or UP. What's the maximum score you can get, if your score is the sum of the squares your path crossed?

Score

+0	+2	0
+3	+1	+4
+2	+5	+1
0	+3	+4

# The Generalizable approach - Optimizing

You can only go RIGHT or UP. What's the maximum score you can get, if your score is the sum of the squares your path crossed?

Best Score

5		
5		
2	8	
0	3	7

Score

+0	+2	0
+3	+1	+4
+2	+5	+1
0	+3	+4

# Takeaways

If you can write a recurrence relation, then we can do DP by saving the states in a table.

$$\text{Distinctways}[i][j] = \text{Distinctways}[i-1][j] + \text{Distinctways}[i][j-1]$$
$$\text{BestScore}[i][j] = \text{Score}[i][j] + \max(\text{BestScore}[i-1][j], \text{BestScore}[i][j-1])$$

Contrast to memoization

# This looks different

Compute the maximum sum  
subarray of an array

1	-2	3	-4	5	1	-2	3
---	----	---	----	---	---	----	---

Sum = 7

# Max sum subarray

1	-2	3	-4	5	1	-2	3
---	----	---	----	---	---	----	---

Best sum in the  
first i positions

0	1	1						
---	---	---	--	--	--	--	--	--

How to fill in the next entry?  
Not obvious, since we are extending  
from the array before it

# Max sum subarray

1	-2	3	-4	5	1	-2	3
---	----	---	----	---	---	----	---

Best sum in the  
first i positions

0	1	1						
---	---	---	--	--	--	--	--	--

Best sum ending  
in this position

0	1	-1	2					
---	---	----	---	--	--	--	--	--

[https://github.com/cpcosu/Weekly\\_Events/blob/master/Autumn%202020/2020-09-22/BestSum.cpp](https://github.com/cpcosu/Weekly_Events/blob/master/Autumn%202020/2020-09-22/BestSum.cpp)

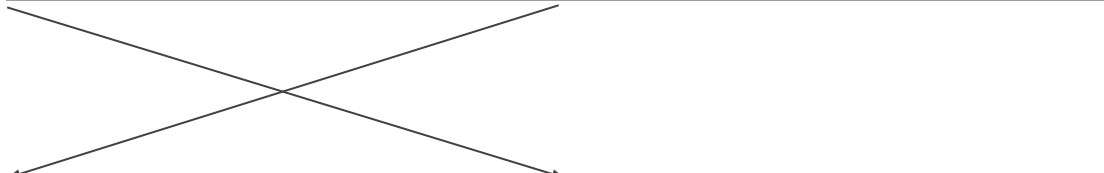

# Application in a problem

Reverse a subarray of this array so as to maximize the sum of the even indexed elements

1	7	3	4	7	6	2	9
---	---	---	---	---	---	---	---

$$\text{score} = 1 + 3 + 7 + 2 = 13$$

4	3	7	1	7	6	2	9
---	---	---	---	---	---	---	---

$$\text{score} = 4 + 7 + 7 + 2 = 20$$

# Observations?

Reverse a subarray of this array so as to maximize the sum of the even indexed elements

1	7	3	4	7	6	2	9
---	---	---	---	---	---	---	---

$$\text{score} = 1 + 3 + 7 + 2 = 13$$

1	6	7	4	3	7	2	9
---	---	---	---	---	---	---	---

$$\text{score} = 1 + 7 + 3 + 2 = 13$$

# Reduction - Case 1

Start from an even index, end before an even index. We must maximize the subarray sum along the new array (6, 1, -1, 7).

$$\text{score} = 1 + 3 + 7 + 2 = 13$$

Best score 26

## Reduction - Case 2

Start from an odd index, end before an odd index. We must maximize the subarray sum along the new array (4, -3, 4).

score = 1 + 3 + 7 + 2 = 13

Best score 18

# A hard problem: Inversion Sum

[https://atcoder.jp/contests/agc030/tasks/agc030\\_d](https://atcoder.jp/contests/agc030/tasks/agc030_d)

Given a sequence and a list of  $Q$  swaps, there are  $2^Q$  ways to perform swaps. What's the sum of the inversion numbers of all  $2^Q$  final sequences (mod  $10^9 + 7$ )?

A: 10, 20, 30, Swaps: (1,2) then (1,3)

	Nothing	(1,2)
Nothing	10, 20, 30 -> 0	20, 10, 30 -> 1
(1,3)	30, 20, 10 -> 3	30, 10, 20 -> 2

Total inversion sum: 6

Given a sequence and a list of  $Q$  swaps, there are  $2^Q$  ways to perform swaps. What's the sum of the inversion numbers of all  $2^Q$  final sequences (mod  $10^9 + 7$ )?

- Just simulate all  $2^Q$  pairs of swaps, then check all pairs at the end to see if they are inverted.
- Time

$$\Theta(2^Q (n^2 + Q))$$

## DP solution

Given a sequence and a list of  $Q$  swaps, there are  $2^Q$  ways to perform swaps. What's the sum of the inversion numbers of all  $2^Q$  final sequences (mod  $10^9 + 7$ )?

- Create tables where the  $i^{\text{th}}$  row and  $j^{\text{th}}$  column in is the number of sequences where  $a_i < a_j$  after the first  $k$  operations.
- We need a way to construct each table from the last one, this seems plausible.

0	1	0
0	0	0
1	1	0

2, 3, 1

0	0	1
0	0	2
1	2	0

Swap(1,3)

2, 3, 1    1, 3, 2

0	2	1
2	0	1
3	3	0

Swap(1,2)

2, 3, 1    1, 3, 2  
3, 2, 1    3, 1, 2

# Recurrence Relation

- $DP[k][i][j]$  - number of sequences where the  $i$  and  $j$ th elements are swapped after the first  $k$  operations.
- Suppose the  $k$ th operation swaps indices  $x < y$

$$\Theta(Q * n^2)$$

Equal to the size of the DP array, so there's no way we can go faster

```
for (int i = 0; i < n; i++)
```

```
    for (int j = 0; j < n; j++)
```

```
         $DP[k][i][j] = DP[k-1][i][j]*2$ 
```

```
         $DP[k][x][y] = DP[k][y][x] = DP[k-1][x][y] + DP[k-1][y][x];$ 
```

```
    for (int j = 0; j < n; j++) {
```

```
        if (j != x && j != y) {
```

```
             $DP[k][j][x] = DP[k][j][y] = DP[k-1][j][x] + DP[k-1][j][y];$ 
```

```
             $DP[k][x][j] = DP[k][y][j] = DP[k-1][x][j] + DP[k-1][y][j];$ 
```

```
        }
```

```
    }
```

## We need to go faster

In the original problem statement, we have

$$1 \leq N \leq 3000$$

$$0 \leq Q \leq 3000$$

Has DP failed us??

# Inspiration!

If we instead compute the expected number of inversions, then we are only updating about  $2n$  terms in the array at each update.

We can compress the first dimension of our code since we don't really use it.

[https://github.com/cpcosu/Weekly\\_Events/blob/master/Autumn%202020/2020-09-22/InversionSum.cpp](https://github.com/cpcosu/Weekly_Events/blob/master/Autumn%202020/2020-09-22/InversionSum.cpp)

$$\Theta(nQ)$$
